

# Mobile

## Lecture 5 – JQuery

Semester I

# Agenda

- **Startup**
- Selectors
- Modifying the DOM
- Events
- Ajax

# What's JQuery

- JavaScript library
- Cross-browser support
- Simple selecting of HTML elements
- Simple event handling
- Simple animation
- Ajax calls to server
- A lot of plugins available

# Jquery file and vsdoc

- <https://jquery.com/download/>
- Using DCN:
  - `<script src="//code.jquery.com/jquery-1.11.3.min.js"></script>`
  - `<script src="//code.jquery.com/jquery-migrate-1.2.1.min.js"></script>`
- Uncompressed version :
  - [http://code.jquery.com/jquery-\[version\].js](http://code.jquery.com/jquery-[version].js)
- Minified version for release:
  - [http://code.jquery.com/jquery-\[version\].min.js](http://code.jquery.com/jquery-[version].min.js)
- IntelliSense :build in since VS2013
- Do not use the CDN links as you sometimes don't have an internet link

# Jquery file and vsdoc cont'

```
<head>
  <script src="//code.jquery.com/jquery-1.11.3.min.js"></script>
  <script src="//code.jquery.com/jquery-migrate-1.2.1.min.js"></script>
</head>
```

- Using the script at the end of the body, after the DOM is build

```
<body>
  <div id="a"></div>
  <script type="text/javascript">
    $('#a').text('nir');
  </script>
</body>
```

\$ - the jquery  
function

# \$ (document) .ready

- Ready – when the DOM is loaded and ready to use (before the images are loaded)

```
<head>
  <script type="text/javascript" src="scripts/jquery
  <script>
    $(document).ready(func1); //callback function

    function func1() {
      $('#a').text('nir');
    }
  </script>
</head>
```

- Or simpler...

```
<head>
  <title>jquery</title>
  <script type="text/javascript" src="scripts/jquery-1.9.1
  <script>
    $(document).ready(function () { //anonymous function
      $('#a').text('nir');
    });
  </script>
</head>
```

# Agenda

- Startup
- **Selectors**
- Modifying the DOM
- Events
- Ajax

# Selectors

- Selectors enables you to select one or more html element\tags in order to perform a manipulation on it.
- Can be done using JS but not as simple as with JQuery
- $\$(selctorExpression) = \text{jQuery}(selctorExpression)$

# Selecting by Tag Name

```
alert($('div').text());
```

```
...  
<div id="firstName">Dexter</div>  
<div id="lastName">Morgan </div>
```

DexterMorgan

- Returns a collection of all the divs
- `.text()` : returns the text value of the element

# Selecting multiple elements

```
alert($('div,p,span').text());
```

...

```
<div id="firstName">Dexter</div>
```

```
<div id="lastName">Morgan</div>
```

```
<p>Debra</p>
```

```
<p>Morgan</p>
```

```
<span>Harry</span>
```

```
<span>Morgan</span>
```

DexterMorganDebraMorganHarryMorgan

- Use `,` to select more than one element. (not necessary by tag name)
- Here: all the divs, ps and spans

# .each()

```
$('#div p,p span').each(function () {  
    alert($(this).text());  
});  
...  
<div id="firstName">  
    <p>Dexter</p>  
</div>  
<div id="lastName">Morgan</div>  
<p>  
    <a>  
        <span>Debra</span>  
    </a>  
</p>  
<p>Morgan</p>  
<p>  
    <span>Harry</span>  
</p>  
<span>Morgan</span>
```

- Will iterate through all the elements and perform the function on each of them. 3 separate alerts!
- *this* – is the element selected. Here we use it as jquery object to get the `.text()` function

# Selecting by Id

```
$('#lastName').css('color', 'red');
```

...

```
<div id="firstName">  
  <p>Dexter</p>  
</div>  
<div id="lastName">Morgan</div>  
<p>  
  <a>  
    <span>Debra</span>  
  </a>  
</p>  
<p>Morgan</p>  
<p>  
  <span>Harry</span>  
</p>  
<span>Morgan</span>
```

Change  
the style

Dexter  
Morgan  
Debra  
Morgan  
Harry  
Morgan

- # - Returns the element with the specified ID
- The fastest way to find an element!

# Selecting start from a specific place

```
$( 'p', '#firstName' ).each( function () {  
    $( this ).css( 'color', 'yellow' );  
});
```

...

```
<div id="firstName">  
    <p>Dexter</p>  
</div>  
<div id="lastName">Morgan</div>  
<p>  
    <a>  
        <span>Debra</span>  
    </a>  
</p>  
<p>Morgan</p>  
<p>  
    <span>Harry</span>  
</p>  
<span>Morgan</span>
```

Dexter

Morgan

Debra

Morgan

Harry

Morgan

- `$( 'element1', 'element2' ) =`  
`$( 'element2 element1' )` - Returns  
`element1` within the `element2`

# Selecting by class

```
$('.names').each(function () {  
    alert($(this).text());  
});
```

```
//much more complicated  
//not all browser supports  
//only HTML5  
//dont have intellisense
```

```
var namesJS = document.getElementsByClassName('names');  
for (var i = 0; i < namesJS.length; i++) {  
    alert(document.getElementsByClassName('names')[i].innerText);  
}
```

...

```
<div id="firstName" class="names">  
    <p>Dexter</p>  
</div>  
<div id="lastName" class="names">Morgan</div>  
<p>  
    <a><span class="spans">Debra</span> </a>  
</p>  
<p class="names">Morgan</p>  
<p>  
    <span class="spans">Harry</span>  
</p>  
<span class="spans">Morgan</span>
```

Dexter

Morgan

Morgan

Dexter

Morgan

Morgan

# Selecting by class cont'

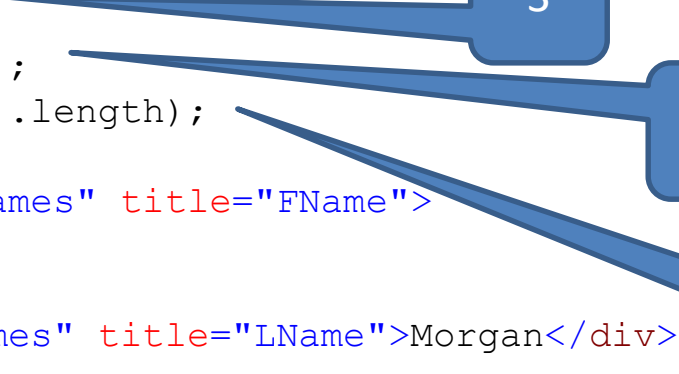

- . - Returns the element with the specified class name
- You can see how simple and convenient is JQuery comparing to JS!!!
- .Length : returns how many elements are in the collection

```
alert($('div.names').length);  
...  
...  
<div id="firstName" class="names">  
    <p>Dexter</p>  
</div>  
<div id="lastName" class="names">Morgan</div>  
<p>  
    <a><span class="spans">Debra</span> </a>  
</p>  
<p class="names">Morgan</p>  
<p>  
    <span class="spans">Harry</span>  
</p>  
<span class="spans">Morgan</span>
```

2

# Selecting by attribute

```
alert($(' [title] ').length);
alert($('div[title] ').length);
alert($('div[title="LName"] ').length);
...
<div id="firstName" class="names" title="FName">
  <p>Dexter</p>
</div>
<div id="lastName" class="names" title="LName">Morgan</div>
<p>
  <a><span class="spans">Debra</span> </a>
</p>
<p class="names" title="pt">Morgan</p>
...
```

- *[attribute]* - Returns the element with the specified attribute
- *[attribute="value"]* - Returns the element with the specified attribute=value

# Selecting by attribute cont'

```
alert($('input[type="text"]').length);
```

2

...

```
<p>first name:<input type="text" id="txtFName"/></p>  
<p>last name:<input type="text" id="txtLName"/></p>  
<p><input type="button" id="btn1" value="push"/></p>  
<p><input type="checkbox" id="chk1"/>choose</p>
```

...

- Only the textboxes

# Selecting by input

```
alert($('input').length);
alert($('input[type="text"]').length);
alert($('select').val());
$('textarea').val($('textarea').val() + " is great!");
```

6

2

LaGuerta

Will add  
the "is  
graet!" to  
the  
textarea

```
...
<p>first name:<input type="text" id="txtFName"/></p>
<p>last name:<input type="text" id="txtLName"/></p>
<p><input type="button" id="btn1" value="push"/></p>
<p><input type="checkbox" id="chk1"/>choose</p>
<p><textarea rows="3" cols="10">season 3</textarea></p>
<p><select>
  <option value=""></option>
  <option value="LaGuerta">LaGuerta</option>
  <option value="Batista ">Batista </option>
</select></p>
<p></p>
```

- `'input'` - returns all the input elements like: text, button, checkbox, radio, select, image, textarea, ...
- `'input[type="value"]'` - Returns the element with the specified type=value. Value = text\radio\checkbox. But not textarea, img,...
- Pay attention that the alerts are fired before the img is shown because the ready() is before the images are loaded to the DOM! This is way only 6 inputs and not 7
- Actually `'input[type="text"]'` is more efficient than `'input[type="value"]'` because it starts with 4 to filter from and not 6!!

# .contains()

```
alert($('div:contains("Mor")').length);
```

2

...

```
<div id="Div1" >Hello Mor</div>
```

```
<div id="firstName" class="names" title="FName">
```

```
  <p>Dexter</p>
```

```
</div>
```

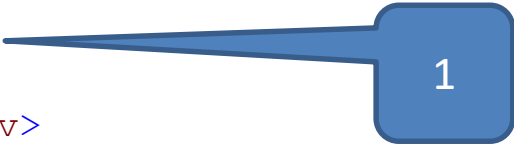

```
<div id="lastName" class="names" title="LName">Morgan</div>
```

...

- *element:contains(string)* - Returns the element that contains a certain string in it's text

# :even \ :odd

```
$( 'div:even' ).each( function () {  
    $( this ).css( 'background-color', 'red' );  
});  
alert( $( 'div:odd' ).length );  
...  
<div id="Div1" >Hello Mor</div>  
<div id="firstName" class="names" title="FName">  
    <p>Dexter</p>  
</div>  
<div id="lastName" class="names" title="LName">Morgan</div>  
...
```

Hello Mor
Dexter
Morgan
Debra

- *element:even* - Returns the even appearance of that elements. 0,2,4...
- *element:odd* - Returns the odd appearance of that elements. 1,3,5,...

# :first-child

```
alert($('span:first-child').length);  
...  
<p>  
  <a><span class="spans">Debra</span> </a>  
</p>  
<p class="names" title="pt">Morgan</p>  
<p>  
  <span class="spans">Harry</span>  
  <span class="spans">Carry</span>  
</p>  
<span class="spans">Morgan</span>
```

2

- *element:first-child* - Returns the element if it is a first child of another element

# :eq()

```
alert($('span:eq(0)').text());  
alert($('span:eq(2)').text());  
...  
<p>  
  <a><span class="spans">Debra</span> </a>  
</p>  
<p class="names" title="pt">Morgan</p>  
<p>  
  <span class="spans">Harry</span>  
  <span class="spans">Carry</span>  
</p>  
<span class="spans">Morgan</span>
```

Debra

Carry

- *element:eq(number)* - Returns the element which is number in the order in the whole DOM. Returns only one element.
- Starts from 0.
- Cant use n variable

# :nth-child()

```
alert($('span:nth-child(1)').text());
alert($('span:nth-child(1)').length);
alert($('span:nth-child(2)').length);

...
<p>
  <a><span class="spans">Debra</span> </a>
</p>
<p class="names" title="pt">Morgan</p>
<p>
  <span class="spans">Harry</span>
  <span class="spans">Carry</span>
</p>
<span class="spans">Morgan</span>
```

DebraHarry

2

1

- *element:nth-child(number)* - Returns the element which is the nth-child of some parent. Can return more than one element.
- Starts from 1.

# :nth-child()

```
$('#span:nth-child(2n)').each(function () {  
    alert($(this).text());  
});  
$('#span:nth-child(2n+1)').each(function () {  
    alert($(this).text());  
});  
...  
<p>  
    <a><span class="spans">Debra</span> </a>  
</p>  
<p class="names" title="pt">Morgan</p>  
<p>  
    <span class="spans">Harry</span>  
    <span class="spans">Carry</span>  
</p>  
<span class="spans">Morgan</span>
```

Carry

Morgan

Debra

Harry

- Can use n variable like: 2n, 2n+1, 3n...

# ^= starts with

```
alert($('div[id^="fi"]').length);
```

2

```
...
```

```
<div id="fid" >Start</div>
```

```
<div id="Div1" >Hello Mor</div>
```

```
<div id="firstName" class="names" title="FName">
```

```
  <p>Dexter</p>
```

```
</div>
```

```
<div id="lastName" class="names" title="LName">Morgan</div>
```

- *element[attribute^="value"]* - Returns elements the their attribute's value begins with "value"

# \$= ends with

```
alert($('input[id$="1"]').length);
```

...

```
<p>first name:<input type="text" id="txtFName"/></p>
```

```
<p>last name:<input type="text" id="txtLName"/></p>
```

```
<p><input type="button" id="btn1" value="push"/></p>
```

```
<p><input type="checkbox" id="chk1"/>choose</p>
```

2

- *element[attribute\$="value"]* - Returns elements the their attribute's value ends with "value"

# **\*= contains**

```
alert($('div[id*="Na"]').length);
```

2

...

```
<div id="fid" >Start</div>
```

```
<div id="Div1" >Hello Mor</div>
```

```
<div id="firstName" class="names" title="FName">
```

```
<p>Dexter</p>
```

```
</div>
```

```
<div id="lastName" class="names" title="LName">Morgan</div>
```

- *element[attribute\*="value"]* - Returns elements the their attribute's value contains "value"

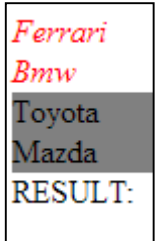

# Agenda

- Startup
- Selectors
- **Modifying the DOM**
- Events
- Ajax

# The example

```
<style>
  .sportCar
  {
    color: red;
    font-style: italic;
  }
  .familyCar
  {
    background-color: Gray;
    font-family: @Batang;
  }
</style>
...

<div class="sportCar">Ferrari</div>
<div class="sportCar">Bmw</div>
<div class="familyCar">Toyota</div>
<div class="familyCar">Mazda</div>
<label>RESULT:</label><div id="result"></div>
```

*Ferrari*  
*Bmw*  
Toyota  
Mazda  
RESULT:

# each() cont'

```
$(document).ready(function () {  
    $('.sportCar, .familyCar').each(function (index) {  
        $('#result').html($('#result').html() + "</br>" + index + ": " +  
$(this).html());  
    });  
});  
...  
<div class="sportCar">Ferrari</div>  
<div class="sportCar">Bmw</div>  
<div class="familyCar">Toyota</div>  
<div class="familyCar">Mazda</div>  
<label>RESULT:</label><div id="result"></div>
```

*Ferrari*  
*Bmw*  
Toyota  
Mazda  
RESULT:  
  
0: Ferrari  
1: Bmw  
2: Toyota  
3: Mazda

- Will iterate through all the chosen elements and perform the function on each of them.
- *this* – is the element selected.
- *Index* –the current iteration's index. Starting with 0.
- Instead of using *this* we can use the second parameter - *element*

```
$(document).ready(function () {  
    $('.sportCar, .familyCar').each(function (index, element) {  
        $('#result').html($('#result').html() + "</br>" + index + ": " +  
$(element).html());  
    });  
});
```

# each() –efficiency consideration!!!

```
$(document).ready(function () {  
    $('.sportCar, .familyCar').each(function (index) {  
        $('#result').html($('#result').html() + "</br>" + index + ": " +  
$(this).html());  
    });  
});
```

- Better to cache the `$('#result')` in order to prevent the searching of it in every loop iteration!

```
$(document).ready(function () {  
    var output = $('#result');  
    $('.sportCar, .familyCar').each(function (index) {  
        output.html(output.html() + "</br>" + index + ": " + $(this).html());  
    });  
});
```

- Now we update the DOM every iteration so to do better we need to use a local variable and update the DOM at the end just once!

```
var output = '';  
$('.sportCar, .familyCar').each(function (index) {  
    output += "</br>" + index + ": " + $(this).html();  
});  
$('#result').html(output);
```

# Attribute

```
$('div').each(function () {  
    this.title = 'Hello';  
});  
...  
<div class="sportCar">Ferrari</div>  
<div class="sportCar">Bmw</div>  
<div class="familyCar">Toyota</div>  
<div class="familyCar">Mazda</div>  
<label>RESULT:</label><div id="result"></div>
```

- Here we use the `this` in order to get to the attribute BUT there is no dynamic (on the `$()`) attribute, instead we can use the `.attr()` function as follows (attribute not properties like `innerText`)

```
$('div').each(function () {  
    $(this).attr('title', 'Hello');  
});
```

- `$(element).attr('attribute', 'value');` //to set
- `$(element).attr('attribute');` //to get

# Attribute cont'

- We could shorten the last modification because the `attr()` will work on all the collection selected any way:

```
$('#div').attr('title', 'Hello');  
$('#div').attr('style', 'color:green');
```

- Multiple modifications are done using JSON
- The style is one of the attributes

```
$('#div').attr(  
{  
  title: 'Hello',  
  style: 'color:green';  
});
```

JSON object looks like this:

```
{  
  property: 'value',  
  property: 'value'  
}
```

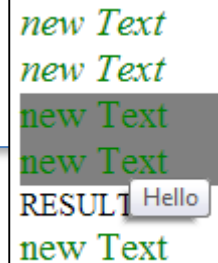

JSON has also nested object (not here)

Ferrari  
Bmw  
Toyota  
Mazda  
RES Hello

# Chaining functions

- After calling a jquery function on an element we can chain another function or more than one like this:

```
$('div').attr('title', 'Hello')  
        .attr('style', 'color:green')  
        .css('font-size', '20px')  
        .text('new Text');
```

*new Text*  
*new Text*  
*new Text*  
*new Text*  
*new Text*

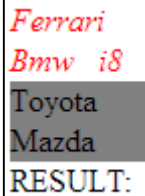

RESULT Hello

# append()

- We can append elements using the *append()* function after a specific element

```
$( '#bmw' ).append( ' &nbsp;&nbsp;&nbsp;<span>i8</span>' );
```

```
...  
<div class="sportCar" id="ferrari">Ferrari</div>  
<div class="sportCar" id="bmw">Bmw</div>  
<div class="familyCar">Toyota</div>  
<div class="familyCar">Mazda</div>  
<label>RESULT:</label><div id="result"></div>
```

Ferrari  
Bmw i8  
Toyota  
Mazda  
RESULT:

# prepend()

- We can prepend elements using the *prepend()* function before a specific element

```
$('#ferrari').prepend('<p>Sport Cars</p>');  
  
...  
<div class="sportCar" id="ferrari">Ferrari</div>  
<div class="sportCar" id="bmw">Bmw</div>  
<div class="familyCar">Toyota</div>  
<div class="familyCar">Mazda</div>  
<label>RESULT:</label><div id="result"></div>
```

*Sport Cars*

*Ferrari*

*Bmw*

Toyota

Mazda

RESULT:

# wrap()

- We can wrap elements using the *wrap()* function around a specific element

```
$('.sportCar,.familyCar').wrap('<p>');  
  
...  
<div class="sportCar" id="ferrari">Ferrari</div>  
<div class="sportCar" id="bmw">Bmw</div>  
<div class="familyCar">Toyota</div>  
<div class="familyCar">Mazda</div>  
<label>RESULT:</label><div id="result"></div>
```

*Ferrari*

*Bmw*

Toyota

Mazda

RESULT:

# remove()

- We can remove elements using the *remove()* function

```
$( '.sportCar' ).remove();  
  
...  
<div class="sportCar" id="ferrari">Ferrari</div>  
<div class="sportCar" id="bmw">Bmw</div>  
<div class="familyCar">Toyota</div>  
<div class="familyCar">Mazda</div>  
<label>RESULT:</label><div id="result"></div>
```

Toyota  
Mazda  
RESULT:

# .css()

- The `css()` function (already saw it) helps us to modify the style.

```
$('div').css("color", "yellow");
```

*Ferrari*  
*Bmw*  
Toyota  
Mazda  
RESULT:

- We can use here the JSON object again

```
$('div').css(  
  {  
    'font-size': '20px',  
    'border': '2px solid black',  
    'margin': '5px'  
  }  
);
```

*Ferrari*  
*Bmw*  
Toyota  
Mazda  
RESULT:  
\_\_\_\_\_

# addClass()

- We can add a new class or more (using spaces) than just one into an element using the *addClass()* function

```
$('.sportCar').addClass('Highlight');  
  
...  
<div class="sportCar" id="ferrari">Ferrari</div>  
<div class="sportCar" id="bmw">Bmw</div>  
<div class="familyCar">Toyota</div>  
<div class="familyCar">Mazda</div>  
<label>RESULT:</label><div id="result"></div>
```

# removeClass()

- We can remove a class or more (using spaces) than just one from an element using the `removeClass('className')` function

```
$('.familyCar').removeClass('familyCar');  
  
...  
<div class="sportCar" id="ferrari">Ferrari</div>  
<div class="sportCar" id="bmw">Bmw</div>  
<div class="familyCar">Toyota</div>  
<div class="familyCar">Mazda</div>  
<label>RESULT:</label><div id="result"></div>
```

Ferrari  
Bmw  
Toyota  
Mazda  
RESULT:

- `removeClass()` without a specific className will remove all the classes of the element

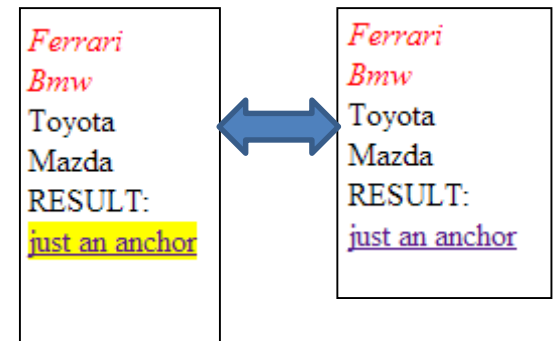

# hasClass()

- We can ask about a class or more (using spaces) than just if it is a part of an element using the *hasClass()* function

```
.Highlight
{
    background-color:Yellow;
}
...
$(document).ready(function () {
...
});
```

```
function anchorClick(div) {
    if ($(div).hasClass('Highlight')) {
        $(div).removeClass('Highlight');
    }
    else {
        $(div).addClass('Highlight');
    }
}
```

```
...
<a href="#" onclick="anchorClick(this)">just an anchor</a>
```

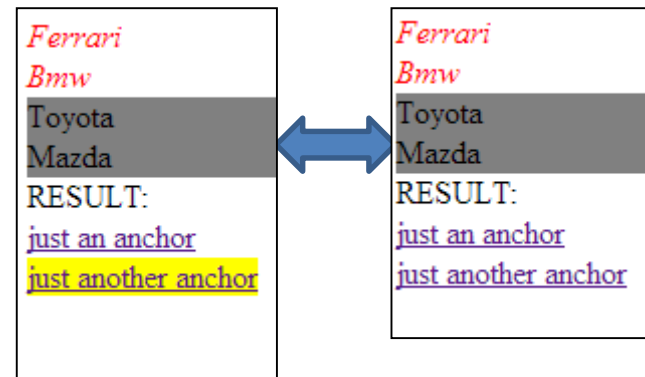

# toggleClass()

- We can toggle (switch on and off repeatedly) a class or more (using spaces) than just one on an element using the `toggleClass()` function

```
.Highlight
{
    background-color:Yellow;
}
...
$(document).ready(function () {
...
});
```

```
function anchorClickToggle(div) {
    $(div).toggleClass('Highlight');
}
```

```
...
<a id="a" href="#" onclick="anchorClickToggle(this)">just another anchor</a>
```

# Agenda

- Startup
- Selectors
- Modifying the DOM
- **Events**
- Ajax

# JavaScript events

- In JS we would have to script a different code for IE v.8 and earlier vs. all the other browsers. JQuery is cross platform and much more compact and simple.

```
<input id="myButton" type="button" value="PUSH" />
<script type="text/javascript">
    //JS event
    var button = document.getElementById('myButton');
    if (document.addEventListener) { //all the other browsers!
        button.addEventListener('click', function () { alert('clicked!'); },
false);
    }
    else { //IE v8 or earlier !
        button.attachEvent('onclick', function () { alert('IE v8 or earlier
clicked!'); });
    }
</script>
```

# Wiring the old fashion

- You can wire the events using the markup, but then its more difficult to find it on the page. Wiring all through the jquery makes it easy to find all in the same place!

```
<input id="myButton" type="button" value="PUSH" onclick="clickFunction()" />
...
<script type="text/javascript">
    function clickFunction() {
        alert('click function');
    }
</script>
```

# click()

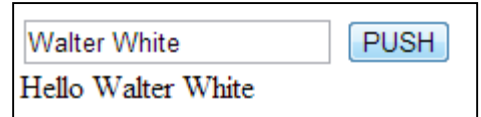

- `click()` – a shortcut for `.on( "click", handler )`

```
$(document).ready(function () {  
    wireEvents();  
});
```

```
function wireEvents() {  
    $('#myButton').click(function() {  
        $('#res').text("Hello " + $('#txtName').val());  
    });  
}
```

...

```
<input id="txtName" type="text" />  
<input id="myButton" type="button" value="PUSH"/>  
<div id="res"></div>
```

Walter White

Hello Walter White

PUSH

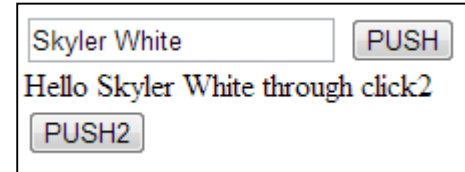

# click() cont'

- Can be used (normally) as definition for the action taken when we click an element but can be also used to call another click function

```
$('#myButton2').click(function () {  
    $('#myButton').click();  
    $('#res').text($('#res').text() + " through click2");  
});
```

```
...  
<input id="txtName" type="text" />  
<input id="myButton" type="button" value="PUSH"/>  
<div id="res"></div>  
<input id="myButton2" type="button" value="PUSH2"/>
```

A screenshot of a web form. It contains a text input field with the value "Skyler White", a button labeled "PUSH", and a text area containing the text "Hello Skyler White through click2". Below the text area is another button labeled "PUSH2".

# change()

- `change()` – a shortcut for `.on( "change", handler )`
- Works on `textbox`, `textarea` and `select`

```
$('#selBB').change(function () {  
    $('#res').text($(this).val());  
});  
$('#txtName').change(function () {  
    $('#res').text($(this).val());  
});  
$('#txtarea').change(function () {  
    $('#res').text($(this).val());  
});
```

```
...  
<input id="txtName" type="text" />  
<input id="myButton" type="button" value="PUSH"/>  
<input id="myButton2" type="button" value="PUSH2"/>  
<p><select id="selBB">  
    <option>Jesse Pinkman</option>  
    <option>Hank Schrader</option>  
</select></p>  
<p><textarea id="txtarea" rows="2" cols="22"></textarea></p>  
<div id="res"></div>
```

The screenshot shows a web form with the following elements:

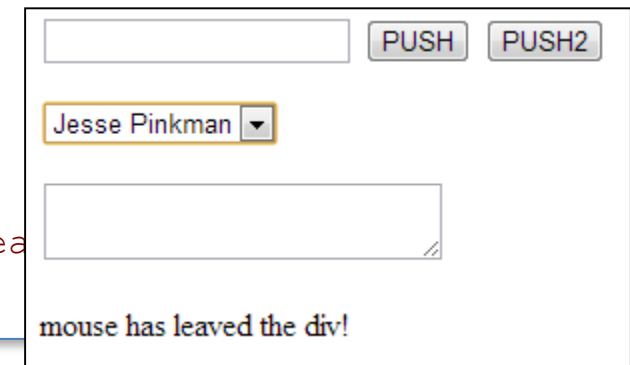

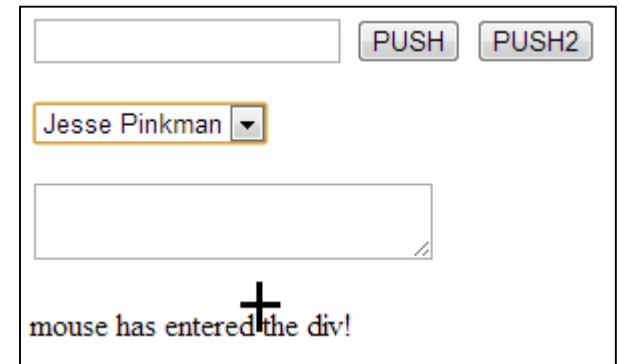

- A text input field containing the text "avi".
- Two buttons labeled "PUSH" and "PUSH2".
- A select dropdown menu with "Jesse Pinkman" selected.
- A text area containing the text "changes are shown when we leave the control!".
- A div element at the bottom containing the text "changes are shown when we leave the control!".

# mouseenter\mouseleave\mouseup\mousedown

- `mouseenter()` – a shortcut for `.on( "mouseenter", handler )`
- `mouseleave()` – a shortcut for `.on( "mouseleave", handler )`
- `mouseup()` – a shortcut for `.on( "mouseup", handler )`
- `mousedown()` – a shortcut for `.on( "mousedown", handler )`

```
$('#res').mouseenter(function () {
    $('#res').text("mouse has entered the div!");
    $(this).css('cursor', 'crosshair');
}).mouseleave(function () {
    $('#res').text("mouse has leaved the div!");
});

...
<input id="txtName" type="text" />
<input id="myButton" type="button" value="PUSH"/>
<input id="myButton2" type="button" value="PUSH2"/>
<p><select id="selBB">
    <option>Jesse Pinkman</option>
    <option>Hank Schrader</option>
</select></p>
<p><textarea id="txtarea" rows="2" cols="22"></textarea>
<div id="res"></div>
```

# event args

- We can use the event argument to get some information like:
  - pageX
  - pageY
  - The id of the element chosen

```
$('#res').mouseenter(function () {  
    $(this).text("mouse has entered the div!");  
    $(this).css('cursor', 'crosshair');  
}).mouseleave(function () {  
    $(this).text("mouse has leaved the div!");  
}).mousedown(function (e) {  
    $(this).text("mouse was pushed down on id=" + $(e.target).attr('id') +  
        " in x=" + e.pageX + " and y=" + e.pageY);  
});
```

mouse was pushed down on id=res in x=127 and y=159

...

```
<p><select id="selBB">  
    <option>Jesse Pinkman</option>  
    <option>Hank Schrader</option>  
</select></p>  
<p><textarea id="txtarea" rows="2" cols="22"></textarea></p>  
<div id="res"></div>
```

# on() and multiple bindings

- We can use the `.on` function to bind several events together
- A bit more efficient than calling the shortcuts – one function call less
- This way we can bind an event dynamically
- Downside is that we can misspell the string
- We can use the event args to manipulate a specific event separately

```
$('#res').on('mouseenter mouseleave mousedown', function (e) {  
    $(this).text("mouse has entered or leaved!");  
    if(e.type=='mousedown')  
        $(this).text($(this).text() + " mouse was pushed down on id=" +  
$(e.target).attr('id') +  
        " in x="+ e.pageX + " and y=" + e.pageY);  
});
```

```
...  
<p><select id="selBB">  
    <option>Jesse Pinkman</option>  
    <option>Hank Schrader</option>  
</select></p>  
<p><textarea id="txtarea" rows="2" cols="22"></textarea></p>  
<div id="res"></div>
```

mouse has entered or leaved!

mouse has entered or leaved! mouse was pushed down on id=res in x=174 and y=157

# off()

- We can use the `.off` function to unbind a specific event

```
$('#res').on('mouseenter mouseleave mousedown', function (e) {
    $(this).text("mouse has entered or leaved!");
    if(e.type=='mousedown')
        $(this).text($(this).text() + " mouse was pushed down on id=" +
$(e.target).attr('id') +
                " in x="+ e.pageX + " and y=" + e.pageY);
});
$('#myButton').click(function () {
    $('#res').off('mousedown');
});
...
<input id="myButton" type="button" value="PUSH"/>
...
<p><select id="selBB">
    <option>Jesse Pinkman</option>
    <option>Hank Schrader</option>
</select></p>
<p><textarea id="txtarea" rows="2" cols="22"></textarea></p>
<div id="res"></div>
```

On mousedown

mouse has entered or leaved!

mouse has entered or leaved! mouse was pushed down on id=res in x=174 and y=157

After myButton was clicked and on mousedown

mouse has entered or leaved!

# off() cont'

- We can use the `.off` function to unbind all events

```
$('#res').on('mouseenter mouseleave mousedown', function (e) {  
    $(this).text("mouse has entered or leaved!");  
    if(e.type=='mousedown')  
        $(this).text($(this).text() + " mouse was pushed down on id=" +  
$(e.target).attr('id') +  
                " in x="+ e.pageX + " and y=" + e.pageY);  
});  
$('#myButton').click(function () {  
    $('#res').text("Hello");  
    $('#res').off();  
});  
...  
<input id="myButton" type="button" value="PUSH"/>  
...  
<p><select id="selBB">  
    <option>Jesse Pinkman</option>  
    <option>Hank Schrader</option>  
</select></p>  
<p><textarea id="txtarea" rows="2" cols="22"></textarea></p>  
<div id="res"></div>
```

On mousedown

mouse has entered or leaved!

mouse has entered or leaved! mouse was pushed down on id=res in x=174 and y=157

After myButton was clicked and on mousedown  
mouseenter or mouseleave

Hello

- *On* and *off* replace the old:
  - *Bind\unbind*
  - *Live\die*
  - *Delegate*
- don't use them any more!

# hover()

- `.hover( mouseInHandler, mouseOutHandler )`

```
<style>
  .Highlight
  {
    background-color: Yellow;
  }
</style>

...
$('#res').hover(
  function () { //mouseenter
    $(this).addClass('Highlight');
  },
  function () { //mouseleave
    $(this).removeClass('Highlight');
  }
);

...
<div id="res"></div>
```

# hover() cont'

- `.hover( mouseInOutHandler )`

```
<style>
  .Highlight
  {
    background-color: Yellow;
  }
</style>

...
$('#res').hover(
function () { //mouseInOut
  $(this).toggleClass('Highlight');
});

...
<div id="res"></div>
```

# Drag and Drop

- `.draggable()` - enables the element to be dragged

```
<link href="styles/jquery-ui%20v1.10.3.css" rel="stylesheet" type="text/css" />
<script type="text/javascript" src="scripts/jquery-1.9.1.min.js"></script>
<script src="scripts/jquery-ui%20v1.10.3.js" type="text/javascript"></script>
```

2 libraries needed

```
...
$('img').draggable({
    helper: 'clone' //with this property can be dropped only on a droppable!!!
});
```

```
...
<div id="src">
    
</div>
<div id="target"></div>
```

# Drag and Drop

- `.droppable()` - enables the element to be dropped into

```
<link href="styles/jquery-ui%20v1.10.3.css" rel="stylesheet" type="text/css" />
<script type="text/javascript" src="scripts/jquery-1.9.1.min.js"></script>
<script src="scripts/jquery-ui%20v1.10.3.js" type="text/javascript"></script>
...
$('#target').droppable({
  drop: function (event, ui) {
    $(this).append(ui.draggable);
  }
});
...
<div id="src">
  
</div>
<div id="target"></div>
```

On drop...

The element

# Try it yourself

## BrBa Puzzle

New Game

# Try it yourself

# Agenda

- Startup
- Selectors
- Modifying the DOM
- Events
- **Ajax**

# Ajax

- *Ajax - Asynchronous JavaScript and XML*
- A way to refresh only part of the page (DOM), so it is more efficient than refreshing whole of it.
- We will use it to send and receive data from the server.
- The data can be of type: JSON, XML, HTML... we will use the JSON format (very efficient)
- The server side will be written in Asp.Net C# using the Web Service technique

# Web Service

- A web service is function that can be called from another computer over the internet.
- We need to know the url and the functions signature

# Web Service cont'

- This is just a student class that we would use in the example

```
class Student
{
    static int count=0;
    public Student()
    {
        ID = count;
        count++;
        Name = "avi" + ID;
        Grade = 80 + ID;
    }
    public int ID { get; set; }
    public string Name { get; set; }
    public double Grade { get; set; }
}
```

attribute

# Web Service cont'

Could be any name

```
[WebService(Namespace = "http://nir.org/")]
[WebServiceBinding(ConformsTo = WsiProfiles.BasicProfile1_1)]
// To allow this Web Service to be called from script, using ASP.NET AJAX,
uncomment the following line.
```

uncomment

```
[System.Web.Script.Services.ScriptService]
public class StudentsWS : System.Web.Services.WebService {

    public StudentsWS () {
        //Uncomment the following line if using designed components
        //InitializeComponent();
    }

    [WebMethod]
    public string GetStudents(int num)
    {
        Student[] students = new Student[num];
        for (int i = 0; i < num; i++)
        {
            students[i] = new Student();
        }
        JavaScriptSerializer serializer = new JavaScriptSerializer();
        string jsonString = serializer.Serialize(students);
        return jsonString;
    }
}
```

JSON

# Web config

- In order to be able to call and **INVOKE** the function from another domain (cross domain) let's say your laptop, we need to add the following to the web.config

```
<system.web>  
  <webServices>  
    <protocols>  
      <add name="HttpGet"/>  
      <add name="HttpPost"/>  
    </protocols>  
  </webServices>
```

# ajax()

- the `$.ajax()` function has some parameters to set using the JSON object:
  - url: the url of the Web Service
  - dataType: the type of the data returned xml, json, script, or html, we use JSON
  - type: Get\POST, we use POST
  - data: the data send to the server
  - contentType: the data type sent to the server, we use "application/json; charset=utf-8"
  - error: function callback
  - success:function callback

# ajax()

```
var WebServiceURL = "StudentsWS.asmx"; //the same as above. only with...

$.ajax({
    url: WebServiceURL + "/GetStudents",
    dataType: "json",
    type: "POST",    //use only POST!
    data: "{ 'num': '" + num + "' }",
    contentType: "application/json; charset=utf-8",
    error: function (jqXHR, exception) {
        //alert("errornir: " + JSON.stringify(jqXHR)); //all the erro...
        alert( formatErrorMessage(jqXHR, exception));
    },
    success: function (data) {
        var str = "";
        studentsObj = JSON.parse(data.d); //or data["d"]
        for (var i = 0; i < studentsObj.length; i++) {
            str += studentsObj[i].ID + "<span class='space'></span>"...
        }
        $("#studentsTable").html(str);
    }
});
```

# ajax() cont'

```
function formatErrorMessage(jqXHR, exception) {  
    if (jqXHR.status === 0) {  
        return ('Not connected.\nPlease verify your network connection.');    } else if (jqXHR.status == 404) {  
        return ('The requested page not found. [404]');    } else if (jqXHR.status == 500) {  
        return ('Internal Server Error [500].');    } else if (exception === 'parsererror') {  
        return ('Requested JSON parse failed.');    } else if (exception === 'timeout') {  
        return ('Time out error.');    } else if (exception === 'abort') {  
        return ('Ajax request aborted.');    } else {  
        return ('Uncaught Error.\n' + jqXHR.responseText);  
    }  
}
```

# Ajax

- The code we saw here will only work *localhost*
- In order to use it on other machine, cross domain we need to use the *JSONP* (JSON with padding) technique. (a bit complicated)
- Luckily, we wont need to do anything while using the *PhoneGap Build*. Because it will do everything for us even with the code we saw here!

# Add extension or add to web.config!!!

```
<configuration>

  <system.webServer>
    <httpProtocol>
      <customHeaders>
        <add name="Access-Control-Allow-Headers" value="accept, content-type" />
        <add name="Access-Control-Allow-Origin" value="*" />
        <add name="Access-Control-Allow-Methods" value="POST, GET, OPTIONS" />
      </customHeaders>
    </httpProtocol>
  </system.webServer>
```
